

C++ Static Members

Exploring `static` data and functions to create class-level shared resources.

Static Data Members

Shared Memory: The Static Data Member

Definition & Purpose

-  Declared ****inside**** the class using the ``static`` keyword, but defined ****outside****.
-  The member is ****common to all objects**** of the class.
-  Memory is allocated ****only once**** for the entire class, regardless of how many objects are created.
-  Its value persists throughout the life of the program.

Class Memory (Static Area)

```
+-----+  
| static int static_var | (1 copy)  
+-----+
```

Object Memory (Heap/Stack)

```
+-----+  
| obj1: |  
|   int normal_var | (copy 1)  
| (points to static_var) |  
+-----+  
+-----+  
| obj2: |  
|   int normal_var | (copy 2)  
| (points to static_var) |  
+-----+
```

Static Data Member Rules

Declaration vs. Definition

A static member must be defined outside the class scope using the scope resolution operator (`::`).

```
class MyClass {  
public:  
    static int count; // Declaration inside  
};  
  
// Definition outside (MUST be done once)  
int MyClass::count = 0;
```

Key Properties

- Must be explicitly defined outside the class definition.
- Can be accessed even if no object of the class exists.
- Cannot be initialized inside the class definition (except for `const static int`).
- Can be used to maintain a global count or a shared property for all objects.

Code Example: Using a Static Counter

```
#include
using namespace std;

class DataDemo {
public:
    int normal_var;
    static int static_counter; // Static declaration

    DataDemo() {
        normal_var = 10;
        static_counter++; // Increments the SAME counter for every object
    }
};

// Static member definition and initialization (MUST be outside)
int DataDemo::static_counter = 100;

int main() {
    DataDemo obj1;
    DataDemo obj2;
```

```
    cout << "obj1: normal_var = " << obj1.normal_var << endl;
```

Static Member Functions

Access Restrictions: Static Member Functions

Definition & Calling

-  Declared with the `static` keyword inside the class.
-  Can be called ****without**** creating an object (using `ClassName::FunctionName()`).

CRITICAL Restriction

-  A static member function ****CANNOT**** access non-static data members or non-static member functions.
-  It can ****ONLY**** access other ****static**** data members or ****global**** variables/functions.

```
| static void myFunc() { |
| // Can access: |
| static_var; (OK) |
| |
| // Cannot access: |
| non_static_var; (ERROR) |
| } |
+-----+
|
| v (Can Access)
+-----+
| Class Memory (Static Area) |
| static_var; |
+-----+
|
| X (Cannot Access)
+-----+
| Object Memory (e.g. obj1) |
```

Code Example: Using a Static Function

```
#include
using namespace std;

class MemberDemo {
private:
    int non_static_var = 5;
    static int static_var;
public:
    static void showStaticVar() {
        cout << "Static var: " << static_var << endl;
        // cout << non_static_var; // ERROR! Cannot access non-static member
    }
};

int MemberDemo::static_var = 25;

int main() {
    // Call without creating an object
    MemberDemo::showStaticVar();

    // You can still call it via an object, but it's less common
    MemberDemo obj;
```

Summary: Non-Static vs. Static

Feature	Non-Static Member	Static Member
Memory	Separate copy for every object.	One single copy, shared by all objects.
Access	Must be accessed via an object (instance).	Accessed via Class Name (`ClassName::member`).
Functions	Can access ANY class member (static or non-static).	Can ONLY access static members or global variables.
Lifetime	Created when object is created, destroyed when object is destroyed.	Created before `main()`, exists until program ends.
